

GitHub Pages DNS Setup for QMM Lab Website

Site URL: <https://qmm.labs.stonybrook.edu>

Purpose: Point the Stony Brook subdomain to the QMM Lab website hosted on GitHub Pages.

Requested DNS change

Because qmm.labs.stonybrook.edu is a subdomain, GitHub Pages recommends a CNAME DNS record, not A records.

Create/update this DNS record:

Record type: CNAME

Host/name: qmm.labs.stonybrook.edu

Target: `<GitHub-owner-or-organization>.github.io`

The CNAME target should be the GitHub Pages default domain only, such as `USERNAME.github.io` or `ORGANIZATION.github.io`. Do not include the repository name in the CNAME target.

If an IP address is required instead

GitHub documents A records for apex/root domains, not as the preferred setup for subdomains. If campus DNS policy requires IP addresses anyway, GitHub's current Pages IPv4 addresses are:

`185.199.108.153`

`185.199.109.153`

`185.199.110.153`

`185.199.111.153`

Optional IPv6 addresses:

`2606:50c0:8000::153`

`2606:50c0:8001::153`

`2606:50c0:8002::153`

`2606:50c0:8003::153`

GitHub repository status

The GitHub Pages custom domain has been set to qmm.labs.stonybrook.edu.

The website repository is configured to deploy through GitHub Pages using GitHub Actions, and the site build includes the custom domain value.

Verification after DNS is updated

After DNS propagation, verify the record with:

```
dig qmm.labs.stonybrook.edu +nostats +nocmd
```

Expected result for the recommended setup: the output should show a CNAME chain from qmm.labs.stonybrook.edu to `<GitHub-owner-or-organization>.github.io` and then to GitHub Pages infrastructure.

DNS changes can take up to 24 hours to propagate. Once GitHub detects the DNS configuration, HTTPS should be enabled/enforced in the repository's GitHub Pages settings.
